

Cloud Vocabulary Card

Day 2 handout. The eight cloud-topology terms you'll use to draft TMD Section 2 — with the TPM-relevant signal each one carries.

Term	What it means	TPM-relevant signal
Region	A geographic cloud location (East US, West Europe)	Drives data residency + base latency to users
Availability Zone (AZ)	A failure-isolated facility within a region	Multi-AZ = survives single facility failure
Multi-region	Deployment across regions	Survives whole region failure; expensive
Managed service	Cloud provider runs it (Azure Database for PostgreSQL, Azure Blob Storage, Azure Service Bus queue)	Less ops cost; less control
Self-managed	You run it on raw compute	More control; more ops cost
Multi-tenant	One deployment serves all customers	Lower cost; harder isolation
Single-tenant	Each customer gets their own deployment	Stronger isolation; higher cost
Edge / CDN	Static and cached content served closest to users	Reduces latency for static assets

The five cloud-topology decisions TMD

Section 2 documents

1. **Region choice** — which region(s)?
2. **Multi-AZ stance** — single AZ, multi-AZ, multi-region?
3. **Managed vs self-managed** — for each component, who runs it?
4. **Multi-tenancy stance** — shared / dedicated / hybrid?
5. **Network boundary** — public, private, VPN, direct connect?

Each decision has a **cost dimension** and a **risk dimension**. The TPM job: surface both, name the trade-off, and frame the choice in customer terms.
