

Pain-Point Severity Matrix

Day 4 · Activity 2 handout. Place each promoted pain on the grid by **Severity** (how bad when it happens) × **Frequency** (how often it happens). Then **color-code each by Addressability** — how much of it we can actually engineer away.

Addressability key: ● Engineer-fixable · ● Partly fixable / needs design · ● Must communicate/live with (not a build fix)

Severity × Frequency grid

	Frequency: LOW	Frequency: MEDIUM	Frequency: HIGH
Severity: HIGH			
Severity: MEDIUM			
Severity: LOW			

Write the pain (or its number) in the cell; mark each with ● / ● / ●.

Reading the grid

- **High × High** = fix first (your Top 3 usually live here).
- **High severity × Low frequency** = rare but painful — decide: engineer or communicate?
- **Low × Low** = deprioritize; don't let these crowd the readout.

"Must live with" notes (red cells)

For every ● pain, write one line on how you'd **communicate** it to the customer instead of building for it:

- _____
- _____
- _____

⚠ If everything lands in the "must fix" (High × High) corner, severity and frequency weren't honestly discriminated — re-score.
